

Au₂Cl₆

Understanding Au₂Cl₆: A Simplified Guide to Gold(III) Chloride

Gold, a precious metal known for its luster and inertness, can surprisingly form compounds that are quite reactive. One such compound is Au₂Cl₆, formally known as gold(III) chloride. While the chemical formula might seem daunting, understanding its structure and properties is achievable with a breakdown of its key features. This article will demystify Au₂Cl₆, providing a clear and accessible explanation of its nature and significance.

1. What is Au₂Cl₆ (Gold(III) Chloride)?

Au₂Cl₆ is the dimeric form of gold(III) chloride. "Dimeric" means it exists as a pair of molecules linked together. Each individual gold(III) chloride unit consists of a gold atom (Au) bonded to three chlorine atoms (Cl). These units are not isolated but rather share chlorine atoms, forming a structure where two gold atoms are bridged by two chlorine atoms. This can be represented as Cl₂Au-Cl-Cl-AuCl₂. The oxidation state of gold in this compound is +3, hence the name gold(III) chloride. It's crucial to distinguish it from gold(I) chloride (AuCl), which has different properties and applications.

Imagine two Lego bricks, each with three studs (representing chlorine atoms) attached. Au₂Cl₆ is like joining these two bricks together by sharing one stud on each. This sharing creates a more stable and less reactive molecule than individual AuCl₃ units would be.

2. Physical Properties of Au₂Cl₆

Au₂Cl₆ is a reddish-brown crystalline solid at room temperature. It's relatively stable in dry air but readily hydrolyzes (reacts with water) to form various gold chloride hydroxides and ultimately gold oxide. This sensitivity to water makes its handling and storage crucial. Its melting point is relatively low, approximately 290°C, at which point it begins to decompose, releasing chlorine gas. This decomposition highlights its reactive nature, particularly under elevated temperatures. Remember that chlorine gas is toxic, so handling Au₂Cl₆ requires careful safety precautions.

3. Chemical Properties and Reactivity of Au₂Cl₆

Au₂Cl₆ is a strong Lewis acid, meaning it readily accepts electron pairs from other molecules. This property is key to many of its chemical reactions. It reacts vigorously with a variety of substances, including water, as mentioned earlier, and also reacts with various reducing agents to form elemental gold. This reduction is often utilized in gold plating and other gold refining processes. It also reacts with organic compounds, forming complexes which can have interesting catalytic properties.

A practical example of its Lewis acidity is its reaction with chloride ions (Cl⁻). This reaction forms tetrachloroaurate(III) ions ([AuCl₄]⁻), a complex anion commonly found in solutions containing gold(III) chloride. This complex formation is exploited in analytical chemistry for the determination of gold.

4. Applications of Au₂Cl₆

The primary use of Au₂Cl₆ is as a precursor to other gold compounds and in various chemical processes. It's crucial in the production of gold-based catalysts used in various organic reactions, including those involved in the synthesis of pharmaceuticals and other fine chemicals. Its ability to form complexes with various ligands (molecules or ions that bind to the central metal atom) makes it valuable in the creation of tailored materials with specific properties. Gold plating, although often achieved through electrochemical methods, can also utilize gold(III) chloride as a source of gold ions.

5. Safety Precautions When Handling Au₂Cl₆

Due to its reactivity and the toxicity of the products it forms upon decomposition (chlorine gas), handling Au₂Cl₆ requires careful attention to safety protocols. It should be handled in a well-ventilated area, and appropriate personal protective equipment (PPE), including gloves, eye protection, and a lab coat, should always be worn. Direct contact with skin or inhalation of the dust should be strictly avoided.

Actionable Takeaways

Au₂Cl₆ is a dimeric form of gold(III) chloride, possessing unique chemical properties. It's a strong Lewis acid, sensitive to moisture, and reactive with reducing agents. Its primary applications involve its use as a precursor in gold chemistry, catalysis, and potentially gold plating.

Safe handling requires proper precautions due to its reactivity and the toxicity of decomposition products.

FAQs

1. What is the difference between Au₂Cl₆ and AuCl₃? While AuCl₃ represents a single gold(III) chloride unit, Au₂Cl₆ is the dimeric form, where two AuCl₃ units are linked together via chlorine bridging. Au₂Cl₆ is the form most commonly encountered in solid state.
2. Is Au₂Cl₆ soluble in water? While it is technically soluble to some extent, it readily reacts with water, undergoing hydrolysis and forming various gold chloride hydroxides. It doesn't dissolve in the same way a typical ionic salt would.
3. How is Au₂Cl₆ synthesized? It can be synthesized by reacting gold metal with chlorine gas under controlled conditions.
4. What are the environmental concerns associated with Au₂Cl₆? Its reactivity and potential for

forming toxic chlorine gas upon decomposition necessitate careful handling and disposal to prevent environmental contamination.

5. Are there any biological applications of Au₂Cl₆? Although less common than other gold compounds, research explores Au₂Cl₆'s potential in targeted drug delivery and specific medical applications. However, its toxicity limits its widespread use in this area.

A pure gold coin contains 0.138 mol of gold. What is its mass? Calculate the mass of gold(III) chloride (Au₂Cl₆) that contains a billion (1.00×10^9) gold atoms. Calculate the mass, in grams, of 1.35 moles of silver. How many grams of silver are contained in 4.25 moles of silver? How many moles of gold are in 4.5×10^{24} atoms of gold? What is the mass, in grams, of 0.034 moles of silver atoms?

Calculate the mass of copper contained in 1.855 grams of copper(I ... Calculate the mass of gold(III) chloride (Au₂Cl₆) that contains a billion (1.00×10^9) gold atoms. Calculate

amount of copper in moles in a 33.9 g pure copper sheet. What is the anhydrous mass of manganese(II) chloride tetrahydrate what is the total mass of manganese chloride tetrahydrate. Use the following data to determine the following.

What mass of AuCl₃ contains 160.9 g of gold? Calculate the mass of gold(III) chloride (Au₂Cl₆) that contains a billion (1.00×10^9) gold atoms. Calculate the mass, in grams, of each of the following: 1.1×10^{23} gold atoms. What mass of iron is contained in 86.6 grams of chalcopyrite, CuFeS₂? What is the mass of 4.32 mol GaI₃? a) 455 g b) 1,230 g c) 1,720 g d) 1,950 g

Calculate the mass in grams of 13.5 mol of vinyl chloride, C₂H₃Cl, ... Calculate the mass of gold(III) chloride (Au₂Cl₆) that contains a billion (1.00×10^9) gold atoms. What is the mass of 1 mole of silver(I) chloride? How many grams are in 3.60 moles of sodium chloride? Calculate the mass, in grams, of MgCl₂ used to prepare a 0.475 L solution which contains 0.095 moles of chloride ions.

What is the anhydrous mass of manganese(II) chloride ... Calculate the mass of gold(III) chloride (Au₂Cl₆) that contains a billion (1.00×10^9) gold atoms. How many grams are in 3.91 mol of sodium chloride? A 6.165-gram sample of an unknown hydrate of cobalt(II) bromide is heated until all the water of hydration is removed. The CoBr₂ that remains has a mass of 4.637 grams.

Calculate the mass of gold(III) chloride (Au₂Cl₆) that contains a ... Calculate the mass (in grams) of 9.37×10^{-4} moles of gold(III) chloride. Calculate the mass, in grams, of 4.86×10^{24} atoms of gold.

Calculate the mass (in grams) of 4.24 mmol of lead (II) chloride (1 ... Calculate the mass of gold(III) chloride (Au₂Cl₆) that contains a billion (1.00×10^9) gold atoms. Calculate the mass (in grams) of 2.31×10^{-5} mole of potassium chromate. Calculate the mass in grams of each of the following samples. a.

Calculate the mass (in grams) of 9.37×10^{-4} moles of gold(III) ... Calculate the mass of gold(III) chloride (Au₂Cl₆) that contains a billion (1.00×10^9) gold atoms. Calculate the number of moles present in 1.26 lb of cobalt(II) chloride. How many moles are in 2.72 mg of gold(III) chloride, AuCl₃? Calculate the moles of NaCl in 5.26 grams of NaCl. Calculate the moles of NaCl in 14.08 grams of NaCl.

Calculate the mass of the 1 electron gained by chloride anion in ... Calculate the mass of gold(III) chloride (Au₂Cl₆) that contains a billion (1.00×10^9) gold atoms. What is the mass of one mole of electrons? Calculate the mass, in grams, of 2.45×10^{24} atoms of lithium. Calculate the mass, in grams, of 1.50×10^{12} lead atoms. Calculate the mass of the following numbers of atoms: 6.022×10^{24} atoms of tantalum.

Determine the mass of gold that can be extracted, if 25.0 g of ... Calculate the mass of gold(III) chloride (Au₂Cl₆) that contains a billion (1.00×10^9) gold atoms. Gold has a molar mass of 197 g/mol. A) How many moles of gold are in a 1.64 g sample of pure gold? B) How many atoms are in the sample? Calculate the mass, in grams, of each of the following: a) $1.1 \times$

1023 gold atoms. b) 2.92×10^{22} helium atoms.
